

Sup Fig 4 | Strains BC11521 and BC11545 showed clear expression in the vulval region and the spermatheca, respectively, that was not reported in the initial assessment. Re-examination of these strains confirmed GFP expression in uv-1 cells for BC11521 and in the spermatheca of BC11545. These features could have been missed in the initial assessment due to mosaicism, since neither strain carry integrated transgene and expression is not seen in all animals (to be validated expression has to be seen in at least 50% of the animals analyzed)
